Complete Search Strategies Overview

- Preprocessing
 - Problem reduction; problem transformation
- General Search
 - Chronological backtracking
- Lookahead
 - Forward Checking, DAC- & AC-Lookahead
- Gather-information-while-searching
 - DDBT, Learning Nogoods, Backmarking
- Hybrids, e.g. FC-BM-CBJ

Pre-processing – before search begins

- Problem reduction
 - 1-consistency is always worth achieving
 - How about 2-consistency? 3-consistency?
- Problem transformation
 - Should redundant constraints be added?
 - With $A < B, B < C$, would adding $A < C$ help?
 - Should the problem be decomposed into sub-problems?
 - Some sub-problems may be tractable
 - E.g. cycle-cutset

Backtracking Search In The 8-Queens Problem

Complete search, till solution found, or “no solution” is concluded

- Place one queen per row
- Place one queen at a time
- Examine each column

Backtrack at dead-ends

Edward Tsang (Copyright)

66

Friday, 06 February 2009

Lookahead Algorithms

- Lookahead so as to detect failure asap
- Reduce remaining problem
- More reduction requires more computation
- Does marginal gain justify marginal cost?
- MAC-Lookahead is effective in general
 - Key: to record support in maintaining AC

Forward Checking

- Algorithm FC:
 - Label one variable at a time
 - After each label $\langle x, v_x \rangle$ is committed to:
 - examine every future variable y
 - remove every value v_y from D_y such that $\langle y, v_y \rangle$ is incompatible with $\langle x, v_x \rangle$
 - Backtrack if any future domain becomes empty
- Found to be quite effective in general

Forward Checking Search

- Problem reduction
 - a major technique
- Combined with search methods
- Reduce domain of future variables
- Detect dead-ends
 - To backtrack early

Dead-end detected after Queen 4 – no legal space for row 6, backtrack...

	A	B	C	D	E	F	G	H

DAC-, AC-Lookahead

- Principle:
 - Do exactly as Forward Checking
 - In addition, after propagating using FC:
 - Maintain DAC or AC in the remaining problem
 - Backtrack if any future domain becomes empty
- DAC, AC can be replaced by k -consistency for any value k

Edward Tsang (Copyright) 70 PR CS LS F U Friday, 06 February 2009

Result of DAC-Lookahead

- 8-Queens Problem
- Three queens have been placed
- Maintaining DAC
- Square 4B is not supported by row 6, hence removable
- The same applies to 5D

	A	B	C	D	E	F	G	H

3				♙				
4	✗	✗ ⁶	✗	✗	✗	✗		
5	✗		✗	✗ ⁷	✗	✗	✗	
6	✗	✗	✗		✗	✗	✗	✗
7	✗		✗		✗		✗	✗
8	✗		✗		✗			✗

Edward Tsang (Copyright) 71 PR CS LS F U Friday, 06 February 2009

Result of AC-Lookahead

- 8-Queens Problem
- Three queens have been placed
- Maintaining AC
- Result: dead-end found in row 7
- Backtrack required – typically remove Queen 3

Dependency-directed Backtracking

Graph showing dependencies between variables A, B, C, D, E, F, G:

- A, B, C, D, E, F, G are nodes.
- Edges: A=F, A=G, B=C, C=D, D=E, E=F, E=G.
- Domains: {1,2,3} for A, B, C, D, E, F, G.

ordering →

1 3 2 3 1 2 ?

where to backtrack to?

- Graph suggests backtracking to F is futile
- E constrains G, but <A,1> & <C,2> are real culprits

Edward Tsang (Copyright) 73 PR CS LS F U Friday, 06 February 2009

Back Jumping

- Jump to the latest culprit

Recorded earliest conflict

Identify the latest culprit, which is 4

Undo queens 5 and 4, continue

Conflict-directed Backjumping

- Problem with Backjumping (BJ):
 - When all values tried, jumping is possible
 - But if labelled, then later backtrack from below, one can only backtrack chronological
- Conflict-based BJ returns causes of failure when backtracking occurs
 - This allows jumping to take place above
- In general form: *Truth Maintenance*

Learning Nogoods

- All conflicts recorded
- Learn Nogoods:
 - (1A,2C,3E,4B)
 - (1A,2C,3E,5D)
 Set covering prob.
- Next, reject (1A,2C,3E,4B)
- In future, avoid (1A,2C,3E,4?,5D)

Backmarking Principles

- Aim: reduce number of constraint checks
 - # of checks often determines cost of search
- Mark(*u,l*): lowest level at which <*u,l*> failed
 - No need to re-consider <*u,l*> as long as the search has not backtracked past this level
- LowUnit(*x*): lowest variable which assignment has been changed since the last time *x* was visited
 - No need to check <*x,v*> against labels before LowUnit(*x*), as they were checked to be ok

Backmarking Data Structures

BM Example

- After 5H, reject all values in 6, as they all failed before queen 5
- So 5H rejected
- Set LowUnit(5) and (6) to 4
- Next try 4G
- only 5B examined
- Start by checking 5B against 4G (not 1A, 2C, 3E, as they were ok)

Search Ordering

- Minimal width ordering
- Minimal bandwidth ordering
- Smallest-domain-variable-first

Width of a Graph, Definitions

- Given an order O :
 - $\text{width of node } x$ is the number of nodes before x and connected to x
 - $\text{width of } O$ is the maximum width for all nodes
- Width of a graph is the minimal width for all ordering

Width, Examples

Ordering $\dots\dots\dots$

Width = 3

Width = 2

Motivation: Min. Width Ordering

- To reduce dependency
- The hope is to reduce backtracking needs
- This is a *heuristic*
 - Sometimes doesn't work
- Ordering (ABC)
 - No backtrack needed
- Ordering (BCA)
 - May need backtrack

Minimal Width Ordering Algorithm

- Repeat**
 - Pick the node with minimum degree
 - Put it to the front of the list
 - Remove all relevant edges
- Until all nodes picked**
- Resulting list has minimal width ordering
 - In reverse order of the picks

Finding Minimal Width, Example

- Build the ordering from the back
- Pick the node with the smallest degree next

Backtrack-free Search

- A **depth first search is backtrack-free** if
 - the level of strong consistency is greater than
 - the width of the ordering used
- An important observation!
- E.g. if width of graph is 3, then maintaining *strong 4-consistency* will allow backtrack-free search
- Trees have width 1
 - hence the *Tree-Search Algorithm*

Bandwidth of a Graph, Definition

- Given an ordering O :
 - bandwidth of node* is the maximum distance to its connected nodes
 - bandwidth of O* is the maximum distance for all nodes
- Bandwidth of a graph* is the minimal bandwidth for all ordering

Bandwidth, Example

Minimal bandwidth ordering

- Aim: to reduce the backtracking distance when backtracking is needed
- Algorithm for achieving MBO is complex
 - (skipped here)
 - Hill climbing is possible
- MBO is upper-bound for *induced width*
 - interesting relations, not to be discussed here

Heuristic: Smallest-domain-first

Used to be called "Fail-first principle"

- Variable ordering heuristic:
 - Pick the variable with the smallest domain to label next
 - Break ties randomly
- Bralez variation:
 - Break ties with variable with maximum degree in the remaining graph

Smallest-domain-first

- Dynamic strategy
 - Different branches may use different ordering
- Known as "Fail-first-principle" (FFP)
 - Now we know it does not succeed by failing first
 - Professor Barbara Smith, Huddersfield
- Effective with Lookahead Algorithms
 - As they dynamically change domain sizes
 - "FC+FFP" used to be seen as most practical

Smallest Domain First, Example
